

Thin Slicing

“Thin-slicing is part of what makes the unconscious so dazzling. But it's also what we find most problematic about rapid cognition. How is it possible to gather the necessary information for a sophisticated judgment in such a short time?”

Malcolm Gladwell,
Blink: The Power of Thinking Without Thinking

Slices Large *By Definition*

Goal: show code “relevant” to *seed* statement

E.g., seed is crash point, cause in relevant code

Slice relevance: all stmts that may affect seed s

- Affect = transitive control + data dependences
- Intuitive: returns executable subset

Problem: slice relevance too broad for user tasks

- Slices often most of the program
- Better analysis won't help!

Thin slicing approach: *Task-centric relevance*

- Focus on direct value flow to seed
- 3.3X, 9.4X reduction in simulated developer effort

A Typical Large Slice

```
String[] readNames(InputStream input) {
    String[] firstNames = new String[100]; int i = 0;
    while (!eof(input)) {
        String fullName = readFullName(input);
        int spaceIdx = fullName.indexOf(' ');
        if (spaceIdx != -1) {
            // BUG: should pass spaceIdx
            String firstName = fullName.substr(0, spaceIdx-1);
            firstNames[i++] = firstName; } }    ...
    return firstNames; }
```

The slice:
Too many
statements!

```
void printNames(String[] firstNames) {
    while (pending) {
        Request r = getQueue();
        print("handling " + r);
        if (r.isImportant()) {
            handleImmediately(r);
        } else {
            queue.add(r);
        }
    }
}

void main(String[] args) {
    while (!queue.isEmpty()) {
        Request r = getQueue();
        handleImmediately(r);
        if (backRequest) return false;
    }
    if (handleRequest()) {
        return true;
    }
    printNames(getState().getNames()); } }
```

Task-Centric Relevance

For tasks, value flow often most important

Thin slice relevance: *producers* for seed

- Producer def: flows a “top-level” value to seed
Top-level: ignoring dereferenced pointers
- Interprocedural def-use chains (including heap)

Program slice →	<code>x = new A();</code>	
Program slice →	<code>z = x;</code>	
Program slice →	<code>y = new B();</code>	← in thin slice
Program slice →	<code>w = x;</code>	
Program slice →	<code>w.f = y;</code>	← in thin slice
Program slice →	<code>if (w == z)</code>	
Program slice →	<code>v = z.f;</code>	← seed

Thin Slicing in Action

```
String[] readNames(InputStream input) {
    String[] firstNames = new String[100]; int i = 0;
    while (!eof(input)) {
        String fullName = readFullName(input);
        int spaceIdx = fullName.indexOf(' ');
        if (spaceIdx != -1) {
            // BUG: should pass spaceIdx
            String firstName = fullName.substr(0, spaceIdx-1);
            firstNames[i++] = firstName; } }
    return firstNames; }
void printNames(String[] firstNames) {
    for (int i = 0; i < firstNames.length; i++) {
        String firstName = firstNames[i];
        print("FIRST NAME: " + firstName);
    }
}
void main(String[] args) {
    String[] firstNames = readNames(...);
    SessionState s = getState(); s.setNames(firstNames);
    if (handleRequest()) {
        printNames(getState().getNames()); }}
```

Are We Done?

Tried several debugging, comprehension tasks

For ~50% of tasks, thin slice alone suffices

For other tasks:

- Often need thin slice + a couple statements
- Can we handle these cases?

Thin Slice Expansion

Thin slices exclude *explainers*

Explainer def: shows *why* producer can affect seed

- Why heap accesses read / write same object, or
- Why producer can execute

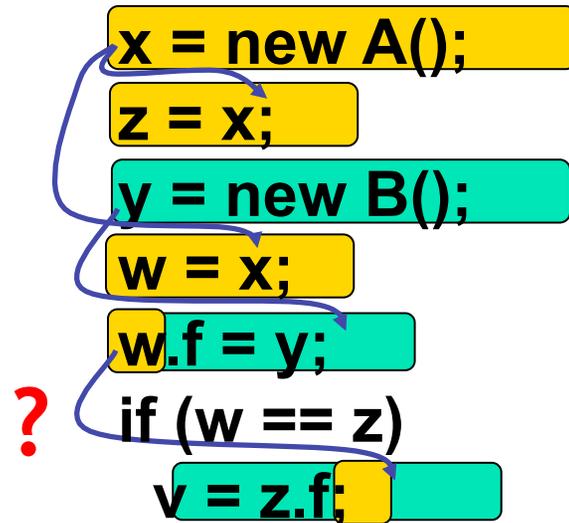

Most explainers not useful for tasks

(Transitive) producers + explainers = whole slice

Expose with incremental expansion

- Guided by user
- Typically, little expansion needed

Explaining Heap-Based Flow

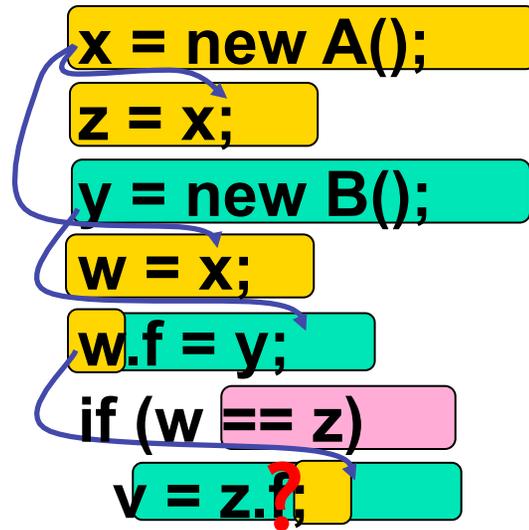

Question: why are base pointers may-aliased?

Answer: two more thin slices!

Shows flow of common object(s)

Incremental: just one level of data structures

Explaining Control Flow

Question: why can producer execute?

Answer: *lexically close* control dependences

- Always sufficient in tested tasks
- Usually, source code navigation enough

Evaluation Methodology

Hypothesis: more effective for developer tasks

E.g., tracking down a bug

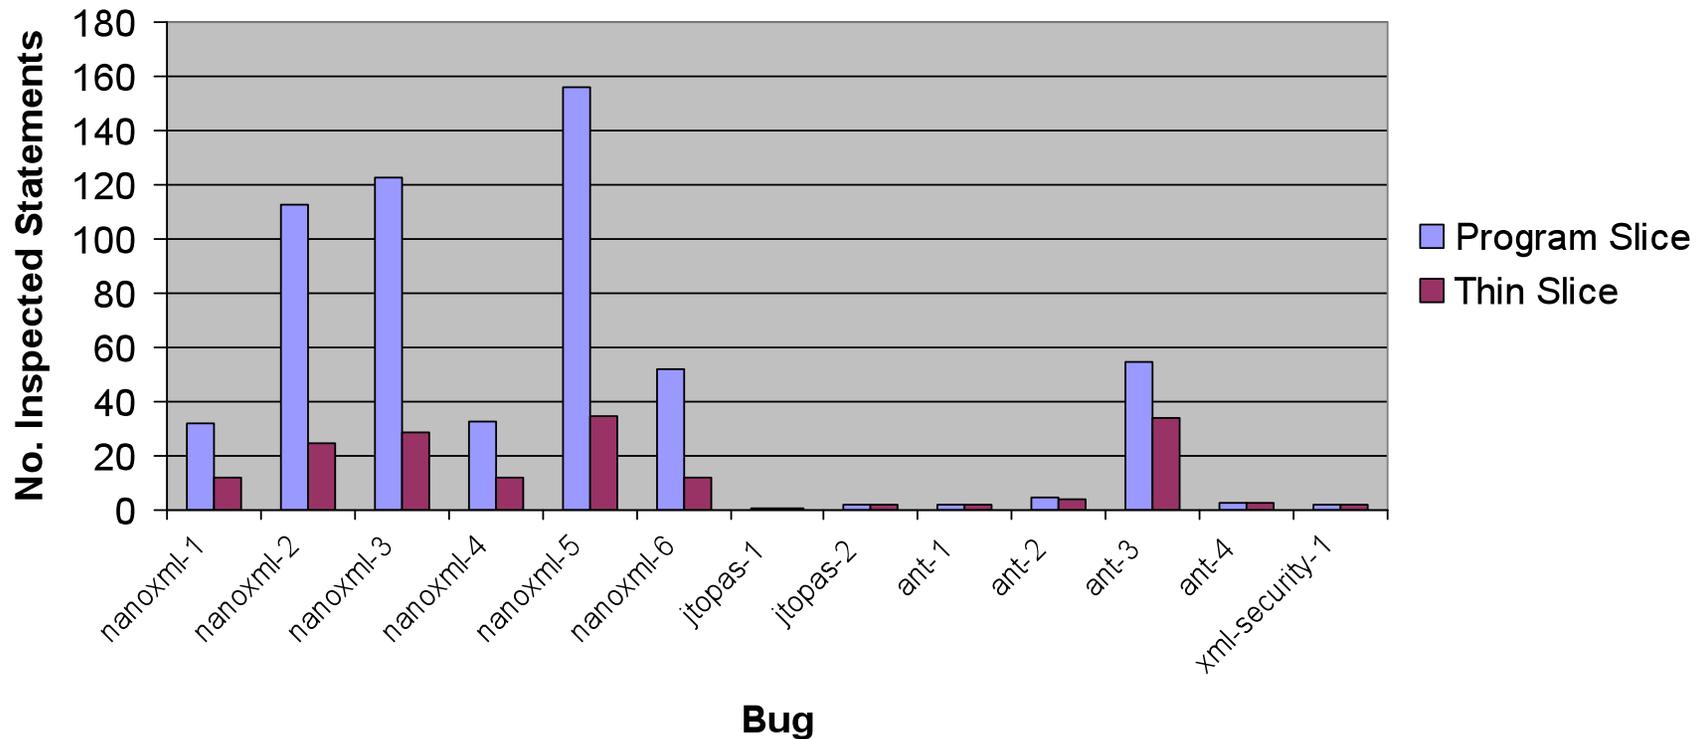

Slice sizes not a good metric

- Developer stops when cause discovered
- Likely to browse dependences, as in Codesurfer

Compare simulated developer effort
(Renieris and Reiss, ASE03)

- BFS from crash point (seed) to cause of bug
- Count reached (“inspected”) statements
- (Include identical control dependences)

Program Slicing vs. Thin Slicing

Mean of 12 inspected stmts / thin slice

Manageable for a developer

Overall, 3.3X fewer inspected stmts

In an understanding experiment, 9.4X fewer inspected stmts

Scalable and Precise Thin Slicing

Two key computations

- Points-to analysis (call graph, aliasing info)
- Reachability on dependence graph

For precision: Context-sensitive points-to analysis

- Used Andersen's + object-sensitive containers
- Just Andersen's) up to 17.2X more inspected stmts

For scalability: Context-insensitive reachability

- Context-sensitive bottleneck: heap accesses as parameters
- In tested tasks, no precision loss observed

Conclusions / Future Work

Program slices too large by definition

Problem: relevance too broad

For thin slicing, only producers relevant

Sufficient for ~50% of tasks

Expand to show useful explainers

Usually close to producers

Bottom line: basis for practical slicing tool

Next steps: Eclipse front end, user study
